

Owner's Manual

DIGGER
Operating Instructions
and
Service Manual

INTRODUCTION ...

This is an electronic game that makes extensive use of digital integrated circuitry and television monitor circuitry. This manual assumes the maintenance technician possesses a general knowledge of solid state circuitry microprocessor, TTL digital integrated circuitry and T.V. monitor concepts. Any individual **not** knowledgeable in these areas **should not** attempt repair of the electronic portion of this game. **It should be noted that any attempt to repair the game in the field without the express consent of the factory will immediately void the warranty!!!**

IMPORTANT NOTES ...

An important service note is posted in this game and is repeated here for emphasis:

If at any time the T.V. screen shows a meaningless display or the game otherwise malfunctions, simply drop a coin into the coin mechanism. This should correct the problem. If not, the game requires service.

The circuitry in this game has been arranged so that the insertion of a quarter through the coin mechanism will reset the restart in the system. This clears up temporary problems caused by power line disturbances, static, etc.

SERVICE TECHNICIAN NOTE:

The system reset circuitry described above requires that the coin counter is attached to the system. If there is a coin counter problem and no replacement is available, the game will function properly if a 10K Ohm resistor is connected across the coin counter input pins to the video logic board.

ALSO ...

Never replace any components with anything other than exact replacement parts. (See Parts List located on Service Schematics.)

Never remove circuit boards/connections while power is on.

Do Not replace the fuse with anything other than the proper value. A blown fuse indicates an overload condition within the game. Replacing the fuse with a higher value can cause severe damage to internal components if an overload occurs.

Always consult the manual before attempting repairs.

Correspondence regarding this game should be addressed to:

8401 Aero Drive
San Diego, California 92123
(714) 277-8700

REPACKAGING INSTRUCTIONS . . .

Arcade
25¼" W x 87" H x 28" D
64.77cm W x 170.18cm H x 71.12cm D
290 lbs./132 kg.

Arcade Version

1. Carefully lay game on its side.
2. Attach pallet with **four** 5/16" - 18 x 1-3/4" bolts, as shown.
3. See Final Recrating Instructions, below.

Mini-Video Version

1. Place game upright inside bottom cover.
2. Slide cover over game. Add protective packing material.
3. Place top cover over side cover.
4. See Final Recrating Instructions, below.

MiniVideo
22" H x 21" W x 20" D
55.88cm H x 53.34cm W x 50.8cm D
80 lbs./36 kg.

Cocktail Version

1. Place game inside carton.
2. Add protective packing material.
3. Place inside protective top cover over unit.
4. Close flaps and secure with shipping tape.
5. See Final Recrating Instructions, below.

Cocktail
22" W x 34" L x 24¼" H
55.88cm W x 93.98cm L x 62.23cm H
80 lb./36 kg.

FINAL RECRATING INSTRUCTIONS . . .

Place game upright. Tape down game keys. Then, crate the game using appropriate shock-absorbent packing material. Include packing on edges of game. **Secure package with strapping.**

Note . . . If the game is to be shipped to Gremlin Industries for service or repair, attach a tag identifying the distributor and indicate the service or repair to be done. Include the full serial number of the game.

All items must be shipped prepaid.

GAME CONCEPT...

DIGGER is a new Gremlin/SEGA game that requires you to dig strategically placed holes within a maze format so you can capture and fill in over the invading creatures before they can attack and destroy your man.

You maneuver your man around the maze with a four-directional joystick. Two push-button controls are used for your shoveling action: one, for the DIG function and another for the FILL function. The maze format changes with every round played.

DIGGER is a Gremlin Multi-Phasetm game that becomes increasingly challenging as your skills improve, as you will see.

The creatures are confined behind a wall. In the first of three rounds of game play, four creatures are let out of the holding area through a gate. You must conquer these four before advancing to the next round, where you face six creatures. Your third round has you battling eight creatures. This process is repeated and the point value increased with each three-round victory. Also, the creatures' speed increases each round. Any contact at all with the creatures will be fatal to your man.

While you are busy digging holes and entrapping creatures, the rest are behind the retaining wall scurrying back and forth. After about three minutes, the gates at each end will open and all of the remaining creatures will stream into the play area at once. However, a skillful player will conquer all of the creatures of each round and the gate will not be a threat.

A DOUBLE SCORE BONUS is awarded if you capture and fill in over the RED creature before any of the GREEN ones. But, this must be the FIRST creature defeated, or the RED creature becomes GREEN and no bonus is awarded.

The point value per creature increases with each three-round phase. The first phase awards 300 points per creature, decreasing to 100 points if not filled over promptly. The second phase awards 500 points per creature, decreasing to 300. And, the third phase awards 700 points, decreasing to 500 points.

A 1000 POINT BONUS is given if you capture four creatures in a row at full point value during any one round.

An EXTRA MAN is given at 5000 points.

When a creature is captured, eight squeaking sounds are heard before the creature escapes from the hole. Five squeaks are required to cover a creature, so you must hurry to the hole and FILL before the fourth squeak, or the creature will emerge and devour your man.

If your FILL is incomplete and another creature passes along the same path, it will pull the other out and your man may be eaten. If a hole is incomplete, it will delay creatures somewhat, depending on the size of the partially dug hole.

On the DIGGER upright and Mini-Video games, two players alternate turns. A player loses his turn when the round is complete, not just when he loses a man.

On the slimline and cocktail tables, DIGGER can be a two-player SIMULTANEOUS PLAY, or ALTERNATE PLAY, as described above. In the SIMULTANEOUS PLAY option, the sum of Player 1 and Player 2 scores are used as one final score. The game play is the same as one-player and either man may FILL a hole, regardless which one dug it. If you select ALTERNATE PLAY action, it is the same as the upright or Mini-Video.

A unique feature of Gremlin/SEGA's DIGGER game is the personalization of HI SCORES. At the end of the game in which the highest score of the machine is topped, the player uses the DIG and FILL buttons to run through the alphabet selecting his three initials. These will remain until that score is topped by another player. In SIMULTANEOUS PLAY, Player 1 enters his initials first, and then Player 2 enters his. Both initials are displayed until their score is beat.

DIGGER SOUNDS

BACKGROUND SOUND is used anytime creatures are present in the maze.

This sound speeds up with the creatures' speed.

An ESCAPE SOUND is used as the creatures rush through the gate into the maze area.

A DOUBLE BONUS SOUND is used when the red creature is the first captured.

Another BONUS SOUND is heard when the 1000 POINT BONUS is awarded.

A beeping CREATURE SOUND that squeaks when a creature falls into a hole.

A SCORING SOUND accompanies the flashing score display after a creature is buried.

A SCREECH SOUND is used when your man is eaten by a creature.

A RELEASE SOUND is used when a creature leaves a hole.

A GAME-OVER BOOM is heard at the end of the game.

NEW GAME BOARDS AND NEW EPROMS...

The following chart shows the two kinds of logic boards Gremlin will use in future games. These will be either a SINGLE VIC board or a DUAL VIC board. Also shown are the possible combinations of Eprom types that Gremlin will be using. The 2 Eprom types are:

- 1) 2708 (holds 8K of memory)
- 2) 2716 (holds 16K of memory).

Obviously, the 2716 holds twice as much information as the 2708, **but the 2 Eproms are not directly compatible**—in other words, you have to replace a 2716 with another 2716, and a 2708 with another 2708. In addition, the 2716 Eprom socket is modified slightly to accept the 2716 Eprom. If it is ever necessary to replace a new Eprom, be sure to specify **2708** or **2716**. These numbers are printed on the Eprom package.

Logic Board Type	Possible Eprom Types Used	Where Used
SINGLE VIC board	1) All 2708's	HEAD-ON 1 HEAD-ON 2 Future games
	2) 2708's and one 2716 (used in combination)	INVINCO DEEP SCAN Future games

The two Eprom types are used since some game programs require a larger memory than that provided with a set of 2708's. Usually, one 2716 provides enough additional memory space to hold a longer program.

POWER SUPPLY MODIFICATIONS . . .

For VIC Logic Boards Only

In order to supply - 5 volts to the VIC logic board, it was necessary to modify the game power supply. The modification simply adds a 7905 - 5 volt regulator (Gremlin part #313-0023) to the power supply chassis; the 7905 is connected into the - 12 volt line at pin 11 of the power supply output connector. **PIN 17 OF THIS CONNECTOR NOW BECOMES THE - 5 VOLT OUTPUT.** The other pins remain the same:

pin 11 = - 12v
pin 12 = + 12v
pin 13 = 2-3 V AC signal
pins 14, 15, 16 = GROUND
pin 17 = - 5v
pins 18, 19, 20 = + 5v

Also, a 8900 ufd filter capacitor has been added to the power supply to provide better + 12 volt regulation.

TRANSFORMER VOLTAGE CONVERSION INSTRUCTIONS . . .

To convert the game transformer to 100, 115, or 230 VAC, refer to the following chart:

- * For 100 volts: Connect the voltage INPUT lines to transformer terminals 1 and 2.
- * For 115 volts: Connect the voltage INPUT lines to transformer terminals 1 and 3.
- * For 230 volts: Connect the voltage INPUT lines to transformer terminals 1 and 4. The fluorescent lamp line must be connected to transformer terminal 3.

ALSO, THE TV MONITOR MUST BE CONVERTED TO THE SAME VOLTAGE INPUT AS THE GAME TRANSFORMER. REFER TO THE MONITOR MANUAL IN THE GAME.

MAINTENANCE PROCEDURES

SINGLE games

I. Power Supply (Refer to drawing #800-0072, sheet 4)

1. Remove output connectors from power supply.
2. Make these initial tests: (GND to BLACK lead on C18, 9000 ufd capacitor)
 - a. +9 VDC on POSITIVE terminal of C18
 - b. +17-19 V on C6 (4700 ufd cap.)
 - c. -17-19 V on C5 (4700 ufd cap.)
 - d. -12 V at output pin 11 (adjustable by trim pot R42)
 - e. +12 V at output pin 12 (adjustable by trim pot R8)
 - f. +5 V at output pins 18,19,20 (adjustable by trim pot R9)
 - g. GND (ground, 0 V) at pins 14,15,16
 - h. 2-3 V AC at pin 13 (Don't forget to change meter scale to AC)
 - i. -5 V at pin 17
3. Check these voltages again with the logic board connected. If any are wrong, a loading condition exists in the logic board, most likely.

II. Logic Board

The following instructions will help you trace down and find most problems associated with the logic board. The procedures are listed by the more common kinds of problems that could arise. Read through all the steps first, then apply them one at a time. The necessary equipment are an oscilloscope and AC/DC voltmeter.

1. NO PICTURE: TV TUBE AND FLUORESCENT LAMP ARE OFF

- a. Plug the game in and check to see that it is receiving 115 (230) VAC. Measure 115 VAC at the input terminals of the game transformer. If it is not present here, proceed to next step.
- b. Check the fuse; if it is good, proceed to next step.
- c. Remove the cover of the junction box in back of the game. Measure 115 VAC on the output of the line filter. If it is not present, the line filter may be bad. Or, one of the AC line connections in the junction box may be loose. UNPLUG the game and re-check these connections.
- d. If the fluorescent lamp still does not operate, turn off game and on again. This usually re-starts the lamp. If it doesn't, turn the lamp in its socket; this will re-seat it for a better connection. Sometimes the lamp works loose during shipment.
- e. An ON/OFF switch for the TV monitor is located on the TV chassis, below the neck of the picture tube. Make sure it is ON.

2. NO PICTURE: TV TUBE AND FLUORESCENT LAMP ARE ON. SCREEN BLACK.

- a. First, make a quick check of the monitor-to-logic board connections: Are all wires making contact with the pin connector? Are the wires secure on the monitor plug-in connector?

- b. Check to be sure U65 is seated in its socket properly, and that no pins are bent. This IC is a Prom that develops the necessary video timing sequences. Usually, if one pin on the chip is out of the circuit, the screen will appear black. Proceed to the next step if this chip is seated correctly.
- c. Inspect the high-voltage lead coming off the monitor's high-voltage transformer. This lead attaches directly to the TV tube. Sometimes, during shipment, this wire is jostled out of contact with the transformer. Turn off the game, and carefully push the wire down toward the transformer to reseal it. Now, check to see if the picture comes on. If it doesn't, proceed to step d.
- d. Using a voltmeter, measure the three voltages powering the logic board. These voltages are: +5v, -5v, +12v, and can be easily measured at the power supply-to-logic board connection. If all voltages are present, go to the next step.
- e. Using an oscilloscope, test for clock signals at the points listed below. For the moment, don't worry about what each signal should look like. We're concerned with finding floating signals, and/or signals that are not present when they should be...and why they are not. The scope setting is .2v/div. @ 5usec with a 10:1 probe. All clock signals, except the video signal, are about 5 volts in amplitude.

- * Check pins 8, 11 of U41. Look for a 1½ volt video signal. If not there, check pin 12 of U41. If it is there, U41 is probably bad.
- * If the signal is not at pin 12 of U41, suspect U48, U42 and U32.
- * Check the following IC's and pins for any floating, or missing signals:

U68 pin 6	U65 pins 1-7,9
U67 pin 5	U49 pins 2,6,10,15
U60 pins 11,12,13,14	U50 pins 2,7,10,14,15.

These chips make up the video timing circuit. Make sure there are no floating, or missing, signals on any of these chips. If there are, suspect the chip is bad.

3. PICTURE APPEARS: COLOR IS DISTORTED; SOME COLORS MISSING

Check the red, blue and green output signals on U42, pins 4,7, and 9, respectively. If no signals are present, suspect U67, U49, U43, U45, U44, U30 or U66.

4. INCOMPLETE PICTURE: RANDOM DISPLAY

Sometimes the game appears on the screen with parts of the picture showing incorrect information. For example, the "HI SCORE" listings display jumbled information, while the rest of the picture is normal. The most likely cause of this problem is one of the 8 RAM IC's U56 through U63. The quickest way to find the bad RAM is simply to replace each IC, one at a time, with a RAM that is known to be good. Be sure not to bend any pins when replacing the IC's. Also, don't overlook the possibility that one of the RAM sockets is bad.

5. RANDOM DISPLAY WHEN GAME IS TURNED ON

- a. Activate the coin switch a few times to see if this clears the picture. If not, turn the game off, then on again. If the jumbled display still appears, proceed to step b.

- b. Check the reset circuit on the logic board (Refer to the schematic). When power is first applied to the game, a reset circuit consisting of Q10, Q11, U55 and U71 is triggered on to reset the microprocessor. This reset signal forces the microprocessor to start at the beginning of the game program. If the microprocessor is not reset, it will still operate...it just won't operate on the right program instructions or data, and will continually display a jumbled pattern on the screen. So, begin by checking for a 3-4 VAC signal at pin 3 of the power supply-to-logic board connector. Follow the signal through Q10 where, at the collector, a sawtooth wave appears. Then, when power is first applied, observe pin 2 of U55 as capacitor C20 slowly discharges to about 3 volts. When this level is reached, U55 is triggered to change states, causing pin 3 to go high, then low. This change is inverted by U54 and, finally, reaches pin 26 of the Z80. Check pin 26 of the Z80 for a low-to-high signal change. If not present, one or more of the reset circuit components are bad. If it is present, proceed to step c.
- c. The following lists some probable causes of the jumbled display pattern:
 - *one or more RAM's
 - *one of the Eproms, U1-8, U20-27

 - *the microprocessor, U53, is bad
 - *U33 or U34 (74LS245) is bad
 - *U19 is bad
 - *check the three operating voltages, +5v, -5v and +12v VDC.

6. GAME DOES NOT COIN UP

- a. A common problem with a game that does not coin up is that the coin switch trip wire is out of adjustment. Usually, all that is necessary is to bend the trip wire up or down, depending on whether a heavier or lighter tension is needed.
- b. There may be a problem in the coin circuit on the logic board. Check U12, pins 3,11, for pulses each time the coin switch is tripped. Also, U11 and/or U12 may be bad. Suspect U45, also.
- c. It is possible that one of the coin counter transistors, Q1 and Q2, is bad. Determine whether or not the counter advances each time the coin switch is tripped.
- d. Don't overlook the possibility of an incorrect, or faulty, coin switch-to-logic board connection; sometimes, these wires work loose from the coin switches.

7. PLAYER CONTROLS NOT WORKING

- a. Check first to be sure all control switch connections are secure. This includes checking the black wires, or ground leads.
- b. If these connections are good, make sure the control panel leads are intact inside the Molex tm connector to the logic board.
- c. If the controls still do not work, suspect U1 on the logic board. However, U1 could be good but might not be receiving the activating pulses from U36, pin 13, or U4, pin 8.

8. GAME SOUNDS NOT HEARD

- a. Check to be sure the sound board output lead is making good contact with the power supply/amplifier connector. Refer to the game wiring schematic.
- b. If these connections are good, check the power supply/amplifier board for any audio signals. Specifically, check U4, Q8 and Q9 on the amplifier board for any game sounds.
- c. If there are none there, suspect U16 on the logic board. Also, check U32 for the pulses that turn on U16.
- d. If these chips appear good, the sound boards are probably bad. Refer to the sound board schematics for each sound's circuit.
