

Power Supply Schematic (037669-01 C)

Regulator Audio II PCB

Regulator/Audio II PCB
The Regulator/Audio II PCB has the function of regulating the +5 VDC logic power to the game PCB and amplifying the audio from the game PCB.

Regulator Circuit
The regulator consists of a voltage pass transistor Q3 and Q3's driver transistor Q1. Q1 accurately regulates the logic power to the game PCB by monitoring the voltage through the + SENSE and - SENSE inputs. The +5 VDC and ground inputs to the regulator regulate the voltage through the harness between the regulator and the game PCB. Resistor R8 is adjusted for the +5 VDC. Once adjusted, the voltage at the input remains constant at this voltage.

Regulator Adjustment

1. Connect a voltmeter between +5 VDC and GND of the game PCB.
2. Adjust variable resistor R8 on the Regulator/Audio II PCB for +5 VDC reading on the voltmeter.
3. Connect a voltmeter between -5 VDC and GND of the game PCB. The voltage should be greater than +5.5 VDC. If ground is not present on both the game PCB and Regulator/Audio II PCB, the voltage will be less than +5.5 VDC.
4. If cleaning PCB edge connectors, connect the voltmeter between the +5 VDC test point of Regulator/Audio II PCB and the GND test point of game PCB. Now connect minus lead of voltmeter to the +5 VDC test point on Regulator/Audio II PCB. From the harness circuit is dropping the voltage to the appropriate harness wire or connector.

Audio Circuit
The audio circuit contains two input channels. Each amplifier consists of a TDA1584P and an effective gain of 22.

From MPU
Address Bus
Sheet 1, Side B

From Sync
Generator
Sheet 1, Side B

Playfield Address Selector

The Playfield Address Selector controls the access to the playfield memory. It allows either the game MPU or the sync generator to scan the playfield memory. The Playfield Address Selector consists of multiplexers P5, and P7 and gate K4.

When 4H on pin 1 of P5 and P7 is low and pin 15 on P7 is low, the Playfield Address Selector receives 8H, 16H, 32H, and 64H on P5 and 16V, 32V, 64V, and 128V on P7 from the sync generator. These signals enable the sync generator circuits to access the playfield memory.

When 4H goes high the game MPU addresses the playfield memory (via AB0-AB9) for the positioning of the graphics. During horizontal blanking (pin 15 of P7 is high) the outputs of P7 (PFA4-PFA7) are held high enabling the motion object circuitry to access the playfield memory for the motion objects to be displayed.

Centipede Playfield RAM

Testing the Playfield RAM

1. Perform the CAT Box preliminary set-up.
2. Set the CAT Box switches as follows:
 - a. Press TESTER RESET
 - b. DBUS SOURCE TO ADDR
 - c. BYTES to 1024
 - d. R/W MODE to (OFF)
 - e. R/W to WRITE
 - f. Key in 0400
 - g. Set R/W MODE to PULSE, then to OFF.
 - h. R/W to READ
 - i. Set R/W MODE to PULSE, then to OFF.
3. If the CAT Box reads an address that doesn't compare, the COMPARE ERROR LED lights, the ADDRESS/SIGNATURE display shows the failing address location, and the ERROR DATA DISPLAY switch is enabled.
4. If the COMPARE ERROR LED does not light, rekey 0400 and repeat the test with the DBUS SOURCE switch set to ADDR. This ensures that the data bits at address 0400 will go high. If the COMPARE ERROR LED does not light after this step, the Playfield RAM is good.

To/From MPU
Data Bus
Sheet 1, Side B

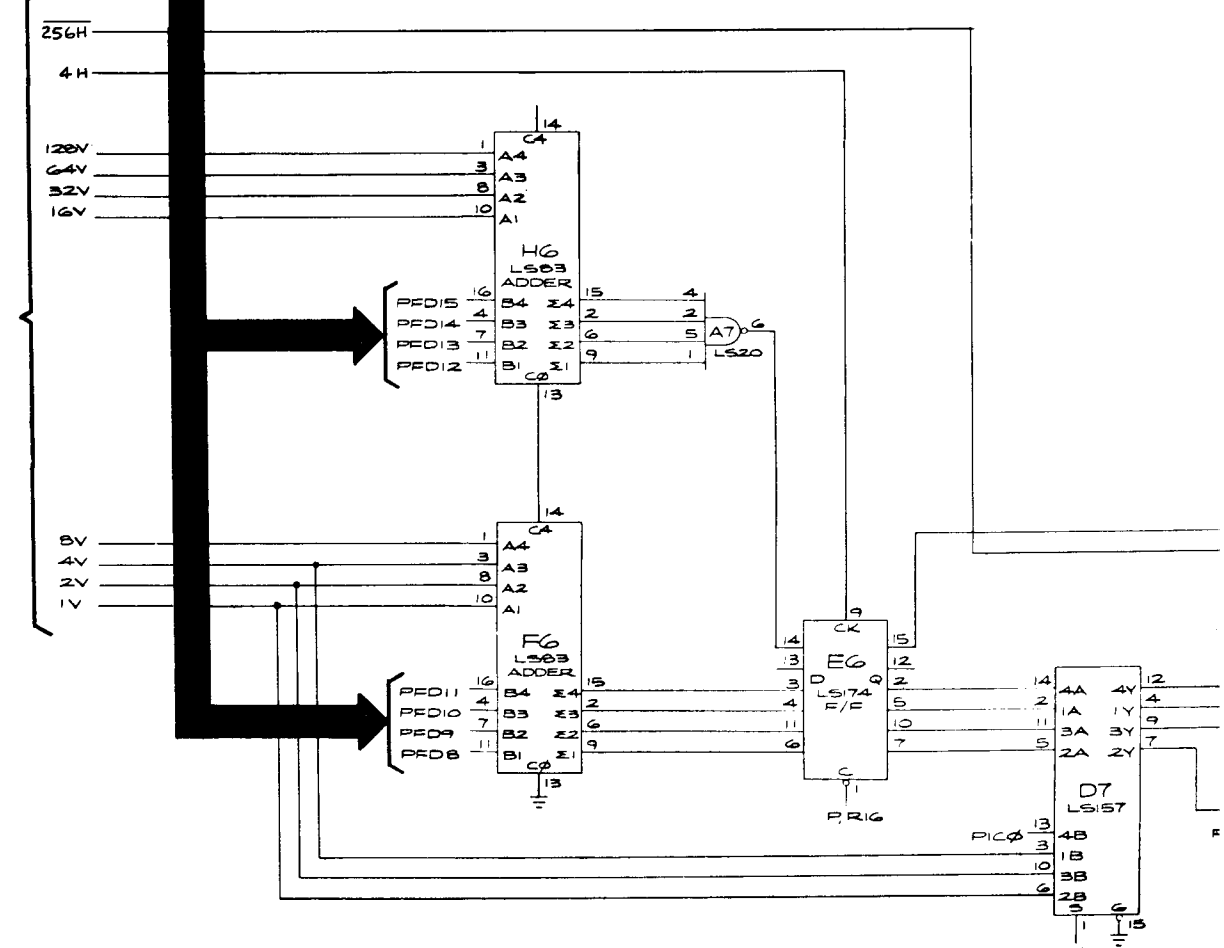

Motion Object Circuitry (Vertical)

The Motion Object Circuitry (vertical) receives playfield data and vertical sync generator circuitry to generate the vertical component of the motion. The output is gated by A7 when a motion object is on one of the sixteen lines latched by E6 to AND gate B7. A low on B7 pin 8 indicates the presence of one of the vertical lines during non-active video time. This signal (MATCH) is used in the picture data circuitry.

When 256H on pin 1 of D7 goes high, 1V, 2V, 4V and PIC0 are selected. When the latched output of E6 is selected. The output of D7 is EXCLUSIVE OR sent to the picture data selector circuitry as motion graphic address (MGA). The input to EXCLUSIVE OR gate E7 is PIC7 from the playfield code multiplexer when high causes the output of E7 to be complimented. For example, if MGA0-MGA3 to go high. This causes the motion object video to bottom.

From Sync
Generator
Sheet 1, Side B

The Playfield (PFD0-PFD31) are played on the motion object circuitry. The output consists of selected outputs.

When 256H is selected output as selected inputs playfield data is selected. The output is low, the input These signals through M6, and N6 for

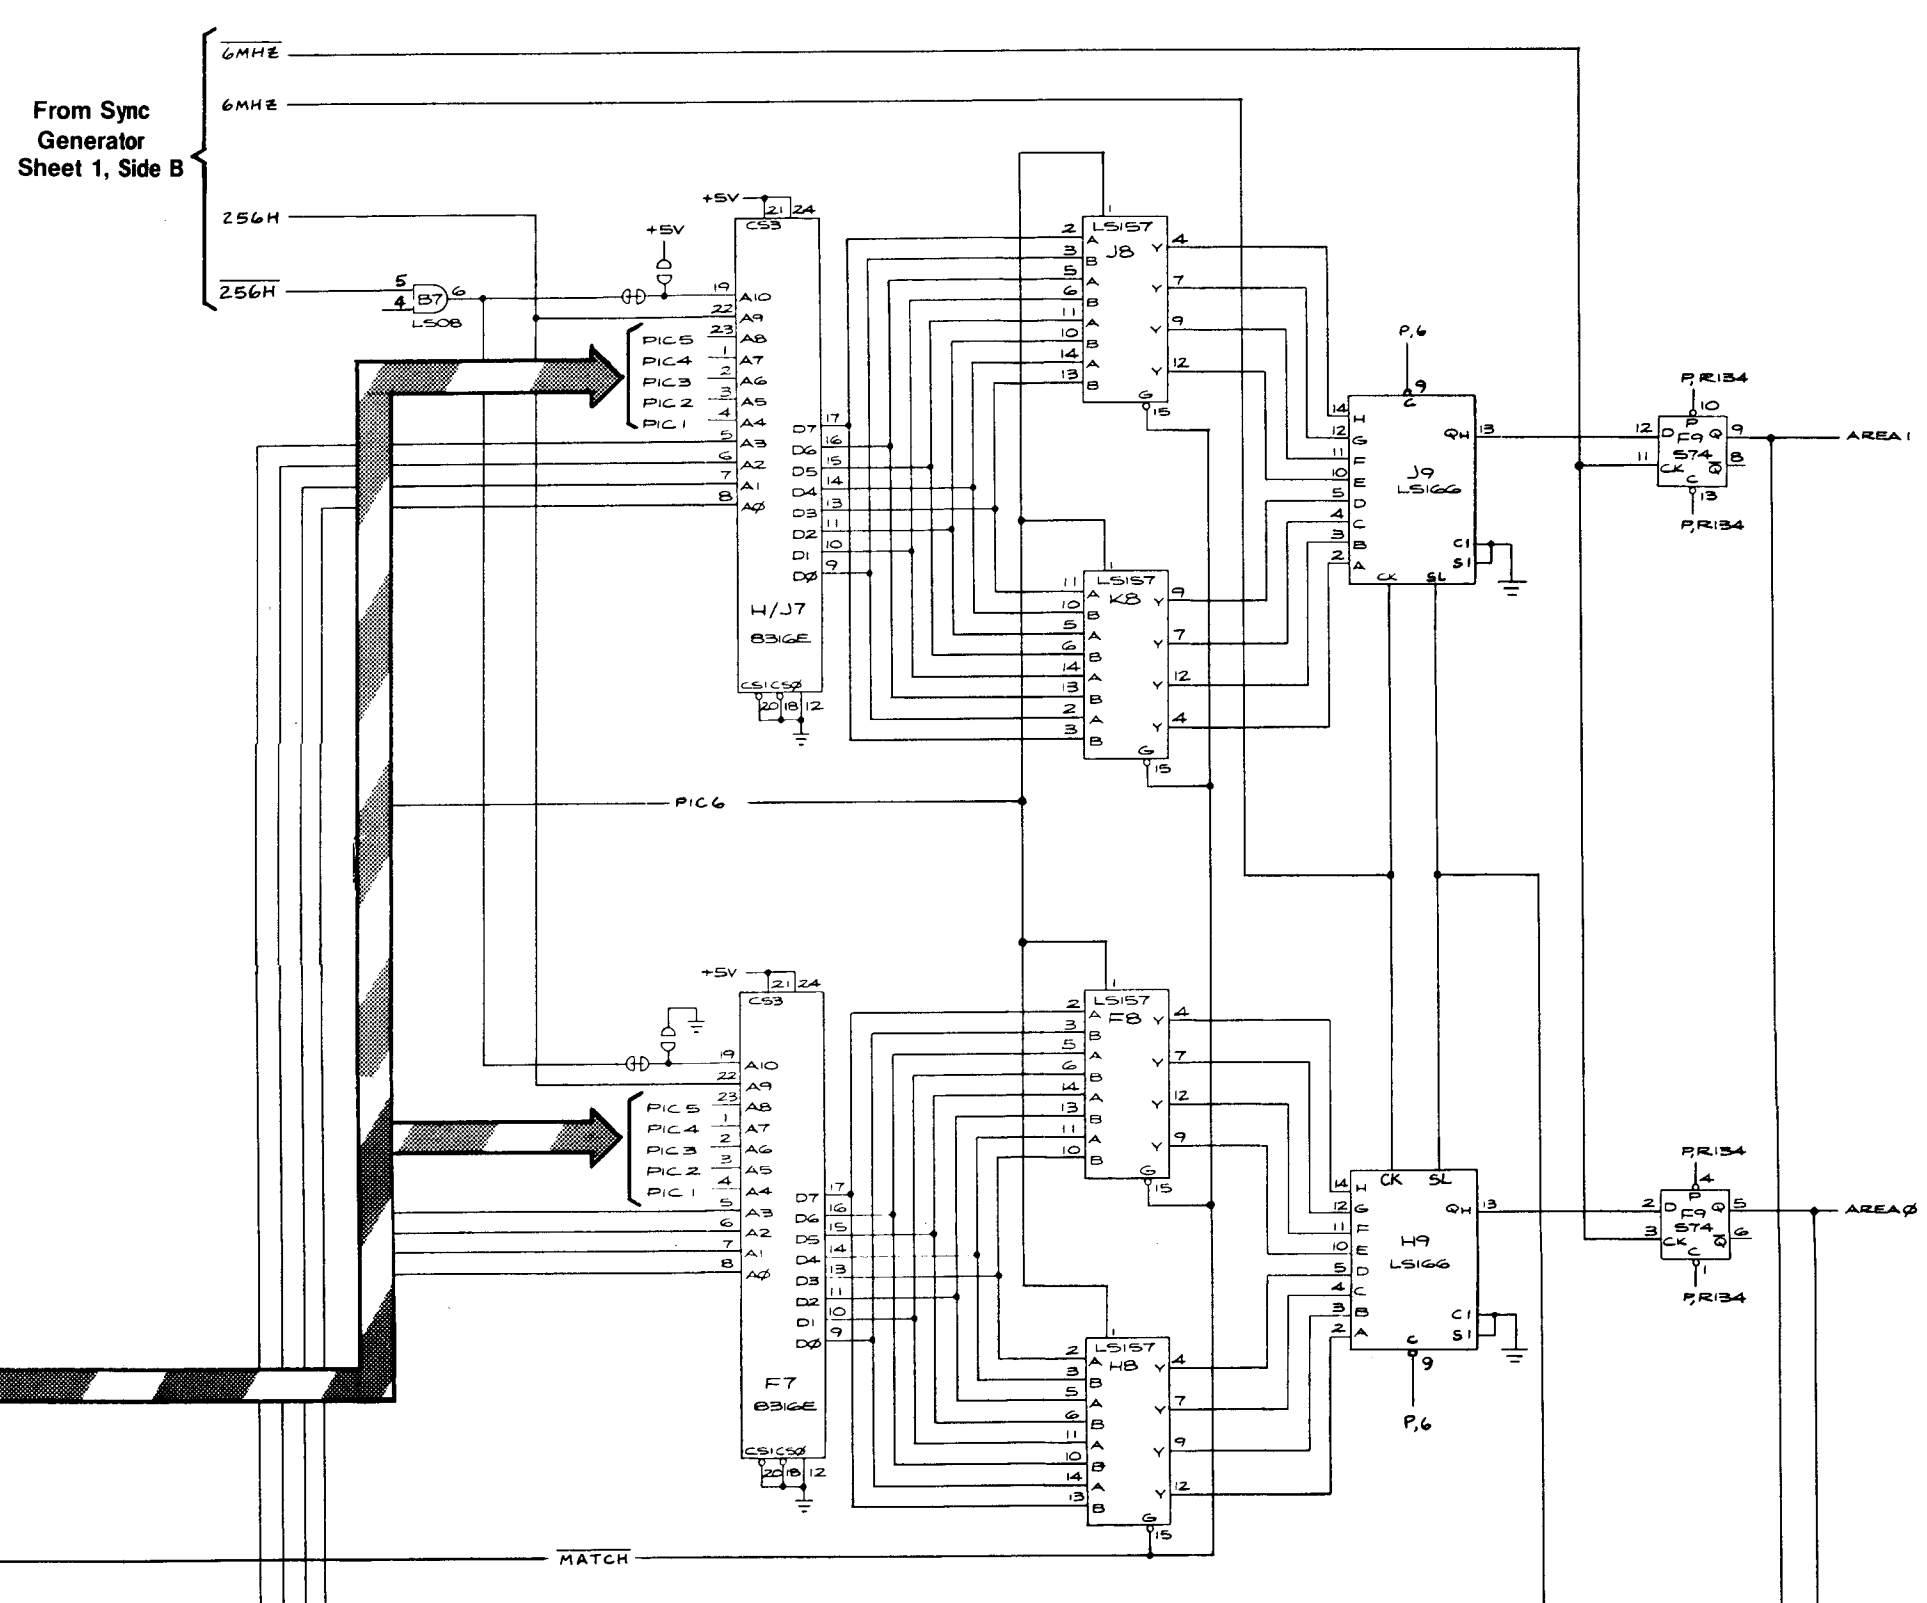

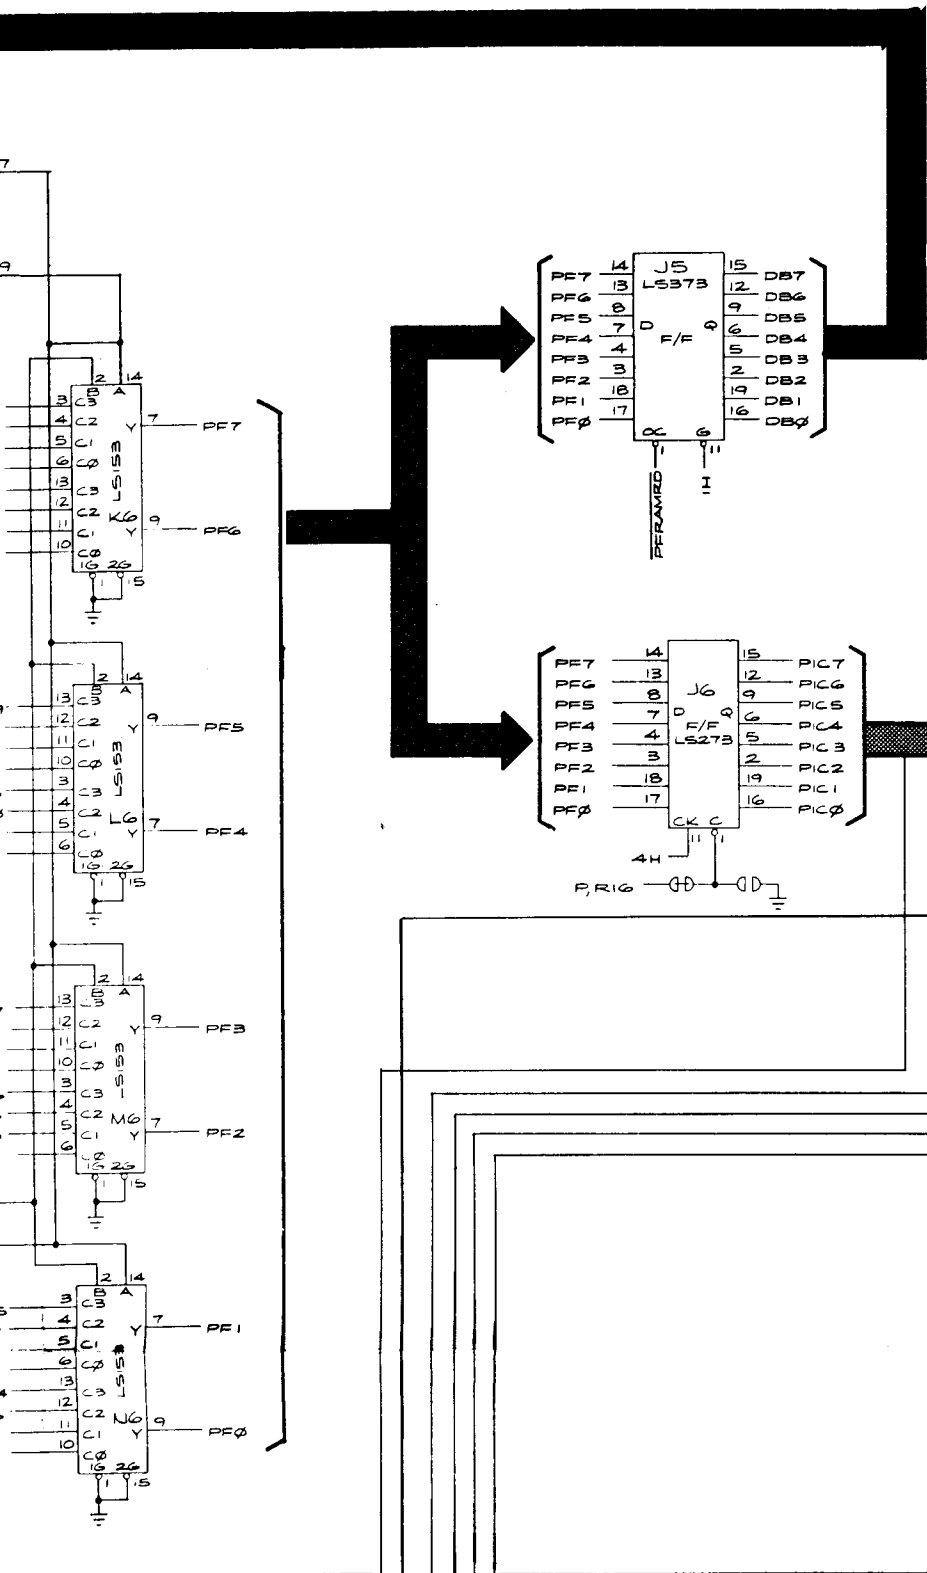

The playfield data is sent to the picture sync generator (DB0-DB7). When picture data PR0

Playfield Multiplexer

The Playfield Multiplexer receives playfield data from the playfield memory (PF0-PF7) and the output (PF0-PF7) is a code that determines what is 1) displayed on the monitor, or 2) read or updated by the MPU. The Playfield Multiplexer selects multiplexers K6, L6, M6, N6 and P6.

When 256H is low and 4H is high, AB4 and AB5 from the MPU address bus is the output from P6. This output is applied to multiplexers K6, L6, M6, and N6. When the MPU is accessing the playfield code multiplexer, the output from P6 is either being read or updated by the MPU. When 256H is high and 4H is low, the inputs on J5 (PF0-PF7) are latched out to the MPU via PROM circuitry. When 256H is high and 4H is high, the inputs (PF0-PF7) are latched to the PROM circuitry.

When 256H is high and 4H is low, the inputs (PF0-PF7) are latched to the PROM circuitry. When 256H is high and 4H is high, the inputs (PF0-PF7) are latched to the PROM circuitry.

Picture Data ROM Circuitry

The picture data ROM circuitry receives picture information, assigns a color code to the information and sends it to the color PROM circuitry. The picture data ROM circuitry consists of ROM devices F7 and H/J7, multiplexers F8, H8, J8, K8, shift registers H9 and J9, and latch F9.

The picture ROMs receive (PIC0-PIC5) from the playfield code multiplexer, MGA0-MGA3 (motion graphics address) from the motion object circuitry, 256H and 256L from the sync generator. PIC0-PIC5 represent the code for the object to be displayed. MGA0-MGA3 set one of eight different combinations of the 8-line by 8-bit blocks of picture video or the 16-line by 8-bit blocks of motion object video.

256H when high selects the playfield picture color codes to be addressed. 256H when low selects the motion object color codes to be addressed. The picture data ROM output D0-D7 on F7 and H/J7 are multiplexed by F8, H8, J8 and K8 and shifted out serially at H9 and J9. This serial output is latched by F9 as AREA0 and AREA1 to the motion object horizontal circuitry and the video output circuit.

Motion Object Circuitry (Horizontal)

The motion object circuitry (horizontal) receives playfield data and horizontal inputs from the motion object video. PFD8-PFD15 compared at F6 and H6. PFD16-PFD23 determine the horizontal position of the motion object. PFD24-PFD29 from the playfield memory determine the indirect color of the motion object. PFD16-PFD23 are latched by B4 and loaded into the horizontal position counters A5 and B5 by a low on pin 9. The horizontal position counters then address video RAMs A6 and B6. These RAMs are loaded with the video data from the particular motion object from shift registers H9 and J9 (which were loaded from the graphics ROM). The output for RAMs A6 and B6 is then sent to the color PROM circuitry as MR0 and MR1.

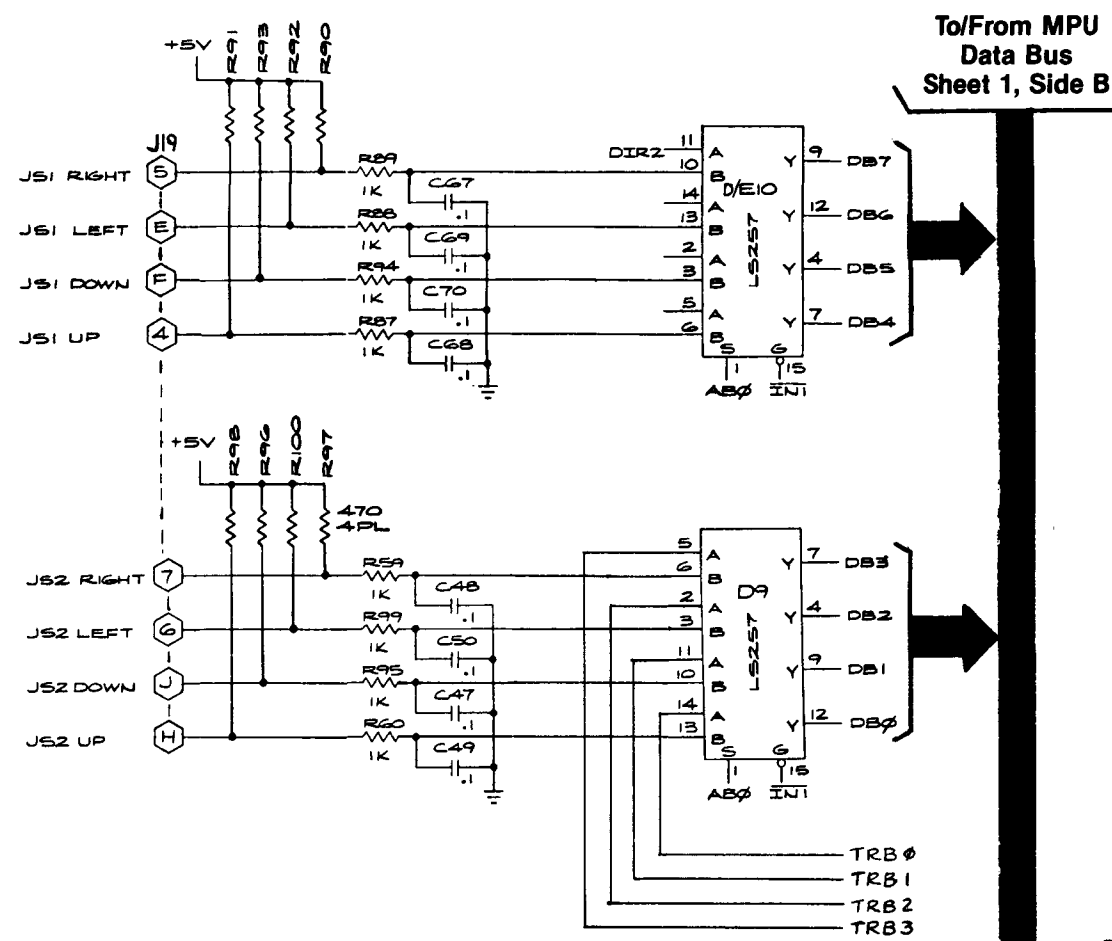

cal)

vertical inputs from the motion object video. PFD8-PFD15 compared at F6 and H6. PFD16-PFD23 determine the horizontal position of the motion object. PFD24-PFD29 from the playfield memory determine the indirect color of the motion object. PFD16-PFD23 are latched by B4 and loaded into the horizontal position counters A5 and B5 by a low on pin 9. The horizontal position counters then address video RAMs A6 and B6. These RAMs are loaded with the video data from the particular motion object from shift registers H9 and J9 (which were loaded from the graphics ROM). The output for RAMs A6 and B6 is then sent to the color PROM circuitry as MR0 and MR1.

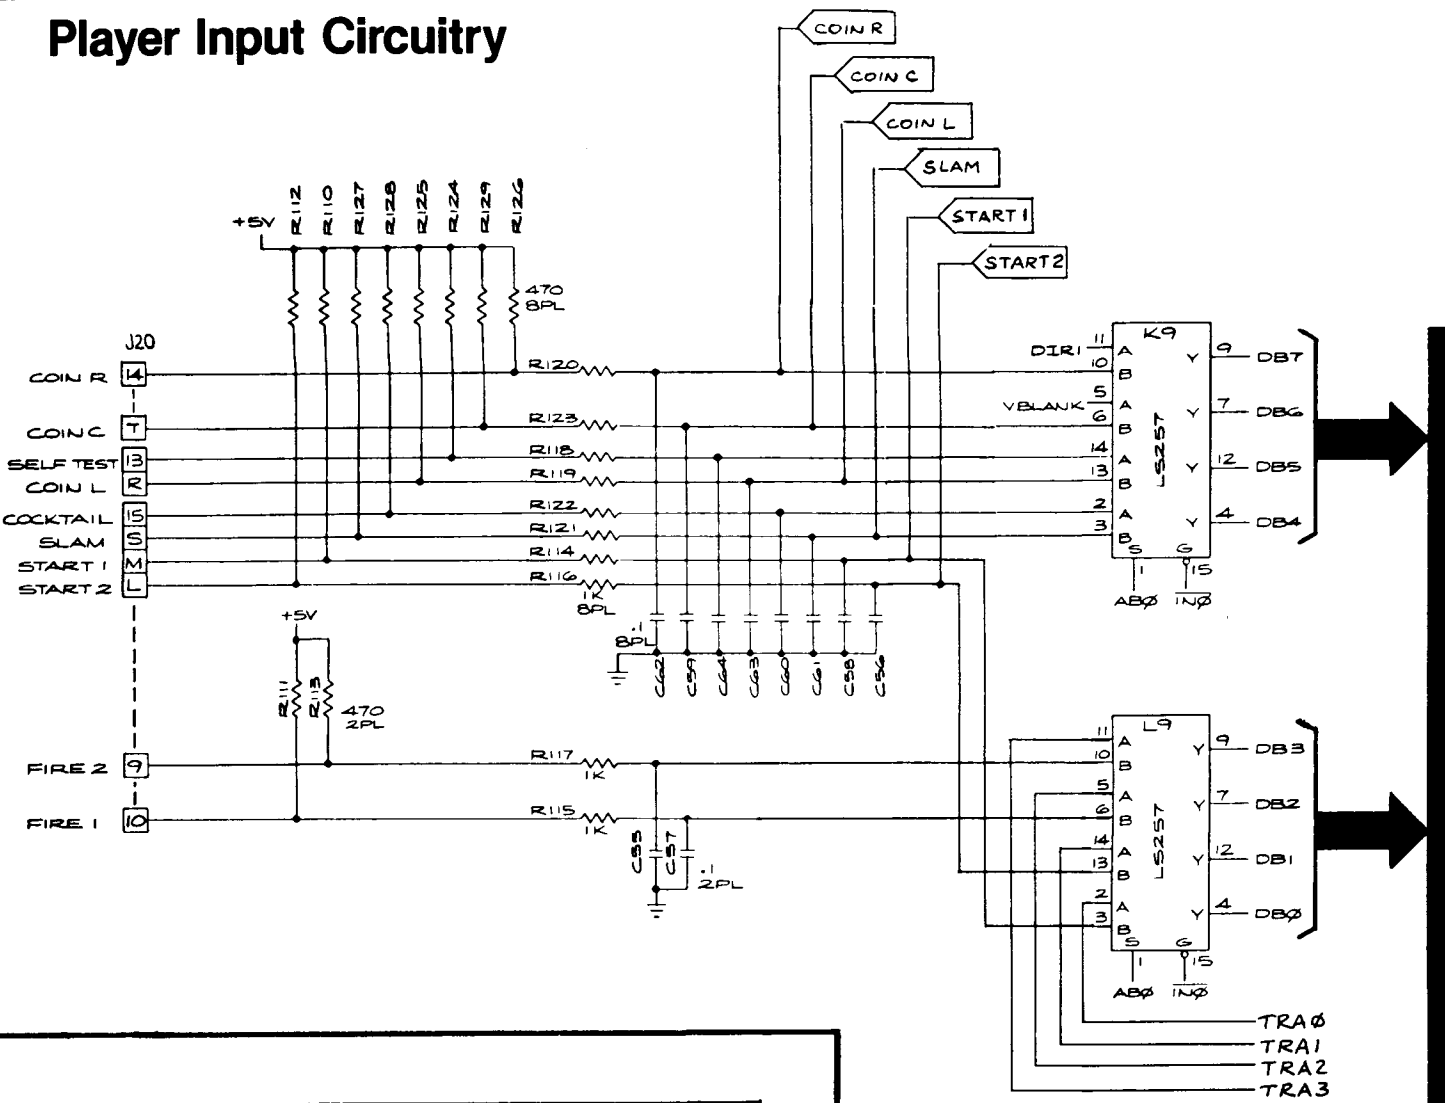

When 256H goes low, the output from P6 is OR gated at E7 and is used to address MGA0-MGA3. The other multiplexer circuitry. PIC7 and MGA0-MGA3 are low, the output from P6 is inverted to be used as the top

Joystick Circuitry

Player Input Circuitry

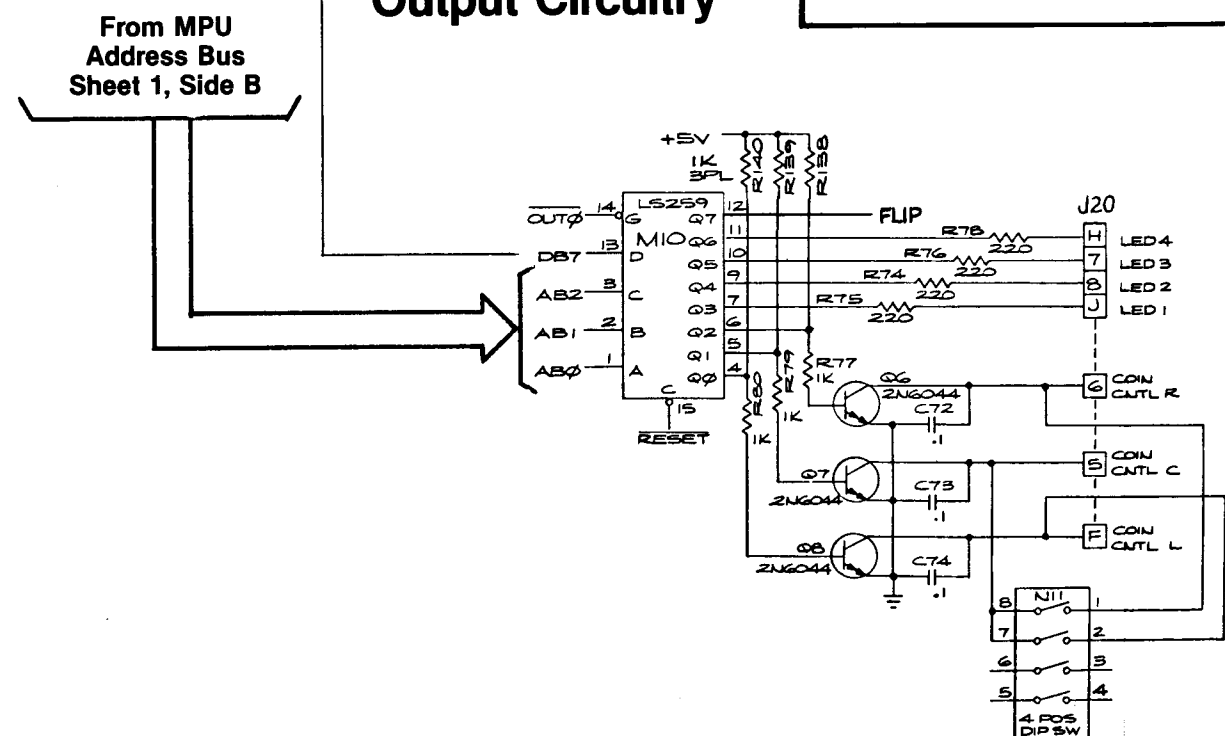

Option Input Circuitry

Testing the Option Switches

1. Perform the CAT Box preliminary set-up.
2. Set the CAT Box switches as follows:
 - a. DBUS SOURCE to DATA
 - b. BYTES to 1
 - c. R/W to READ
 - d. Key in address 0800 (N9) or 0801 (N8)
 - e. R/W MODE to STATIC
3. Activate the switch while monitoring the DATA DISPLAY. The DATA DISPLAY will change if the switch is operating properly.

Coin Counter Output Circuitry

Coin Counter Output Circuit

This circuit consists of coin counter drivers Q6, Q7, and Q8 and data latch M10. The circuit is addressed by the MPU on ABO-AB2 and written by the MPU on data line DB7. When the input to a driver is clocked high, its collector goes low grounding the return of the coin counter in the coin door.

Mini-Trak Ball™ Circuitry

Testing the Mini-Trak Ball™ Inputs

1. Perform the CAT Box Preliminary Set-up.
2. Set the CAT Box switches as follows:
 - a. DBUS SOURCE to DATA
 - b. BYTES to 1
 - c. R/W to READ
 - d. Key in address 0C00 (vertical) or 0C02 (horizontal)
 - e. R/W MODE to PULSE
3. Spin the Mini-Trak Ball™ while monitoring the DATA DISPLAY. The DATA DISPLAY will change if the Mini-Trak Ball input is operating properly.

Testing the Player Inputs

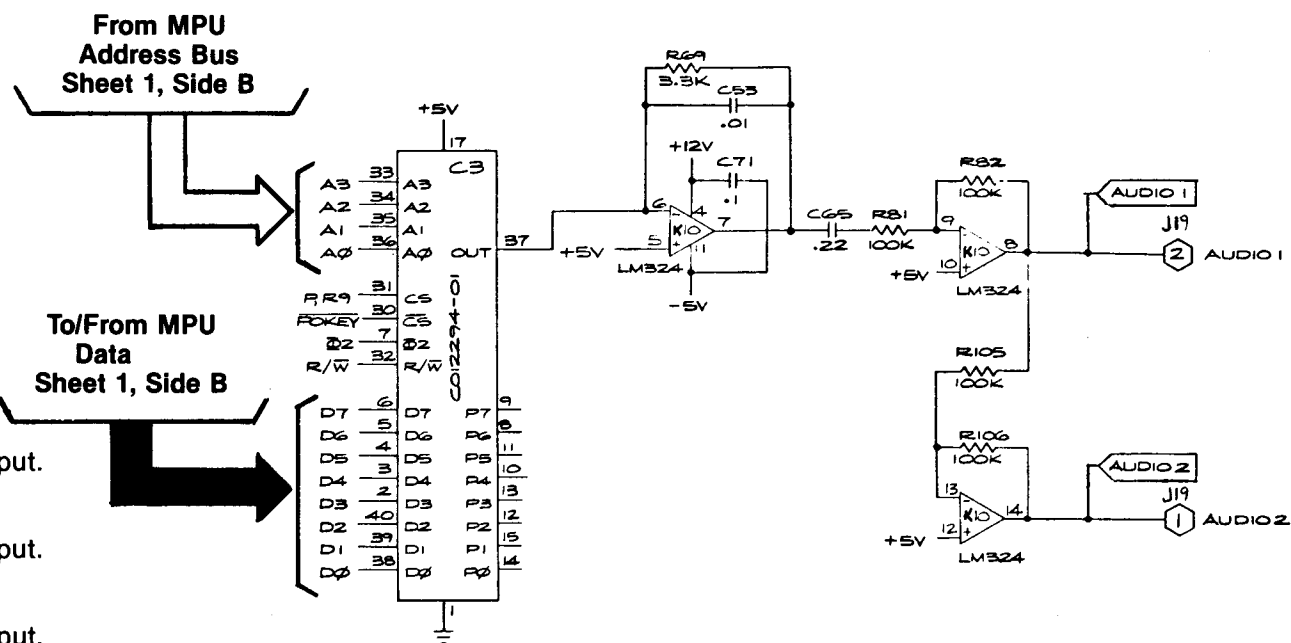

- Perform the CAT Box Preliminary Set-up.
- Set the CAT Box switches as follows:
 - DBUS SOURCE to DATA
 - BYTES to 1
 - R/W to READ
 - Key in address 0C00 (self-test switch only) or 0C01 (all others).
 - R/W MODE to STATIC
- Activate the following player input switches, one at a time, while monitoring the DATA DISPLAY:
 - Coin Right
 - Coin Left
 - SLAM
 - FIRE
 - START 1
 - START 2
- The DATA DISPLAY will change if the switches are operating properly.

Testing the Audio Outputs

- Perform the CAT Box preliminary set-up.
- Set the CAT Box switches as follows:
 - DBUS SOURCE to DATA
 - BYTES to 1
 - R/W to WRITE
 - Key in address or press ADDRESS INCR
 - Press DATA SET
 - Key in data
 - Set R/W MODE to PULSE, then to OFF.
 - For each address, repeat sequence starting at Step d.

ADDRESS	DATA	RESULTS
100F	00	
100F	03	
1000	55	
1001	AF	Pure tone is heard from channel 1 output.
1001	00	Channel 1 output is turned off.
1002	55	
1003	AF	Pure tone is heard from channel 2 output.
1003	00	Channel 2 output is turned off.
1004	55	
1005	AF	Pure tone is heard from channel 3 output.
1005	00	Channel 3 output is turned off.
1006	55	
1007	AF	Pure tone is heard from channel 4 output.
1007	00	Channel 4 output is turned off.

Audio Output Circuitry

◀ Denotes a test point

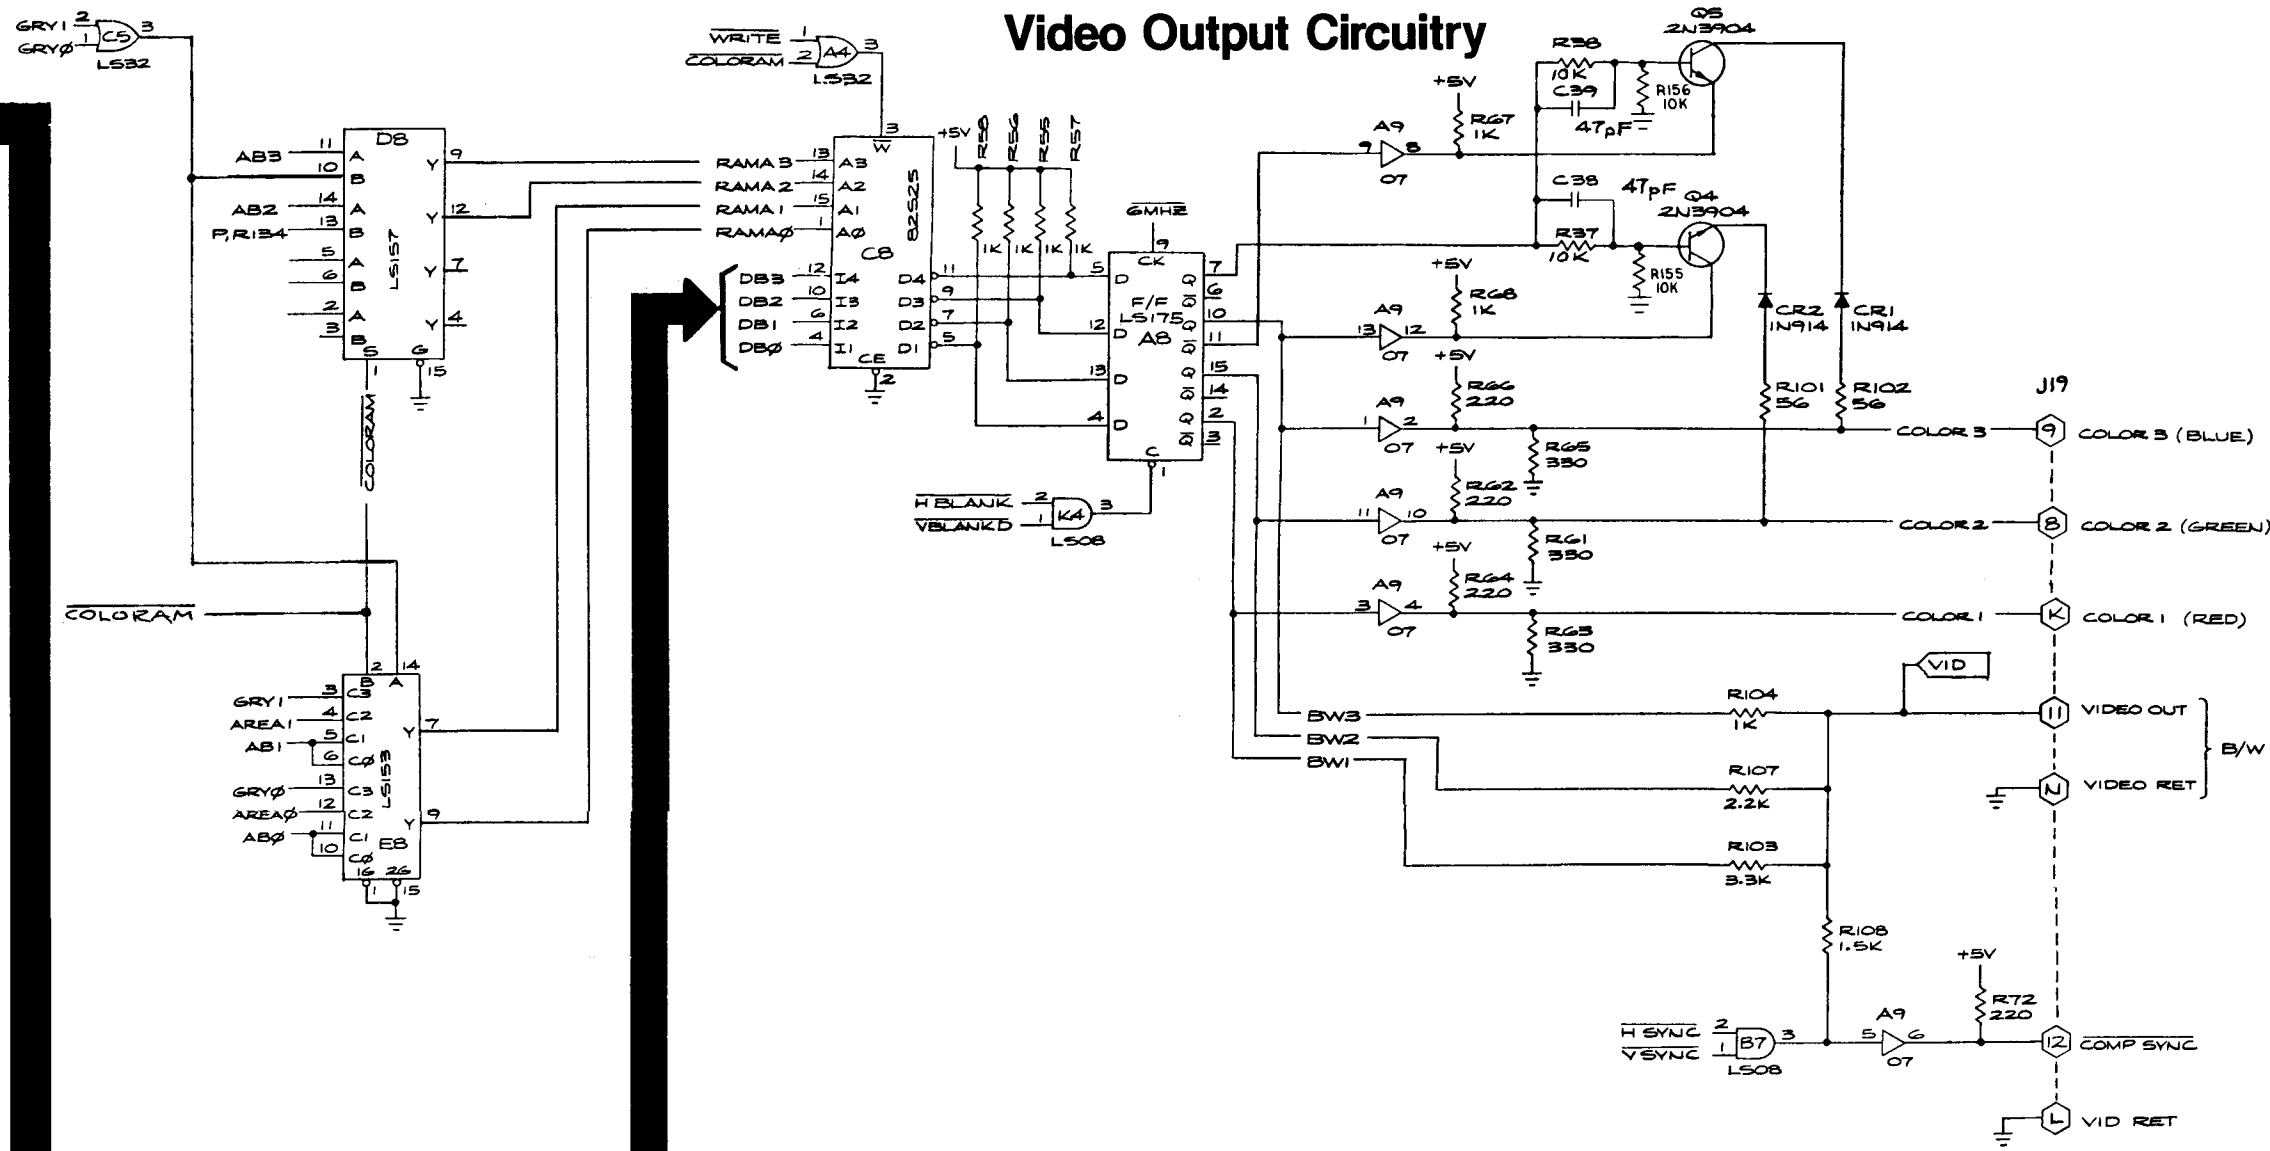

The video output circuit receives motion object, playfield, address and data inputs and produces a video output to be displayed on the game monitor. In order to read out of the color RAM, GRY0 and GRY1 from the motion object circuitry are multiplexed with AREA0 and AREA1 from the playfield circuit by E8. The output, selected by GRY0 or GRY1, is RAMA0-RAMA3 (RAM ADDRESS).

RAMA0-RAMA3 are applied to color RAM C8. The colors red, green, blue and an alternate color bit are outputs. The three color bits are latched by A8 as the game video in the three basic colors (or shades of gray in a black and white monitor). When the alternate color bit (C8 pin 11) is active, an alternate shade of blue or green is available.

The following conditions, along with the various combinations of COLOR 1 (red), COLOR 2 (green) and COLOR 3 (blue), provide 6 extra colors for a total of 14.

- If A8 pin 11 is low, transistor Q5 conducts and draws current from COLOR 3. The result is a pale blue when COLOR 1 and COLOR 2 are off.
- If A8 pin 10 is low, transistor Q4 conducts and draws current from COLOR 2. The result is a pale green when COLOR 1 and COLOR 3 are off.

Video Output Circuitry

High Score Memory Circuitry

The High Score Memory circuit stores the three best scores and other pertinent information. These scores are saved even if power is removed from the game. The High Score Memory circuit consists of an erasable reprogrammable ROM E5, latches E4, H4, J4, buffer H5 and timer A11.

A11 produces a 0-15V square wave at a 1V rate. This signal, when +15V, forward biases diode CR5 and allows capacitor C86 to charge to -29V. When the signal is 0V, CR5 is cutoff and CR4 is forward-biased which causes C84 to develop a charge. C84 charges to approximately -28V. This is the potential required for EAROM C0 to operate.

The MPU addresses the EAROM (AB0-AB5) when a low EAADDR gates WRITE2 at gate A4. The trailing edge of the gated pulse latches the address information to the EAROM E5 via J4. Data is latched by H4 at the same time. The EAROM mode (read, write or erase) is determined by DB0-DB3 at latch E4. A low EACONTROL gates WRITE2 at gate A4. The trailing edge of this gated pulse latches the data into the EAROM E5 via latch H4.

Data is read from the EAROM when EAREAD on pin 1 of buffer H4 goes low.

From MPU Address Bus Sheet 1, Side B
